

## 6-4 First Identification of Quantum States in Superheavy Nuclei — Nuclear Structure Studies for Superheavy Nuclei through $\alpha$ - $\gamma$ Spectroscopy —

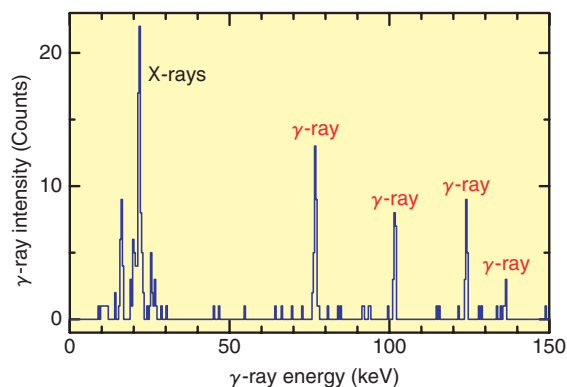

**Fig.6-5 Production of  $^{257}\text{No}$  and  $\alpha$ - $\gamma$  coincidence measurement**

The  $^{257}\text{No}$  nuclei were produced by bombarding a  $^{248}\text{Cm}$  target with a  $^{13}\text{C}$  beam, and transported into a detector station within 1 s using the gas-jet transport technique.  $\alpha$ -particles and  $\gamma$ -rays were detected with high efficiency using Si and Ge detectors, respectively.

The very heavy nuclei containing more than 100 protons are called “superheavy nuclei”. The superheavy nuclei are very unstable because of Coulomb repulsion among the many protons. Thus, they cannot exist without an additional stabilizing effect that originates from nuclear shell structure. How heavy nuclei can exist? How stable are they? The answers strongly depend on the shell structure of superheavy nuclei.

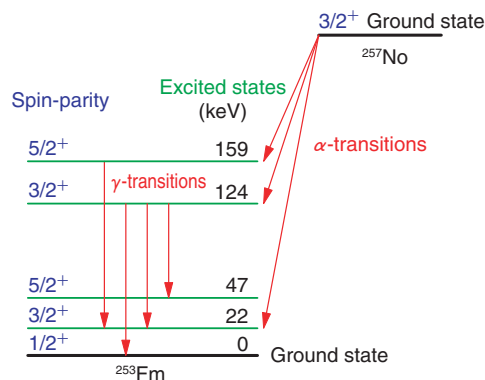

Since the production of superheavy nuclei is extremely difficult, the discovery of the superheavy nuclei was the first aim in previous studies. However, beyond this, if excited states of superheavy nuclei are investigated in detail, the shell structure of superheavy nuclei can directly be clarified. In this work, we have successfully measured  $\gamma$ -rays from the  $\alpha$  decay of nobelium-257 ( $^{257}\text{No}$ ), an isotope of the 102<sup>nd</sup> element, and investigated its quantum level structure. This is the first detailed spectroscopic study of superheavy nuclei.

The  $^{257}\text{No}$  nuclei were produced by bombarding a curium-248 ( $^{248}\text{Cm}$ ) target with a carbon-13 ( $^{13}\text{C}$ ) beam accelerated by the JAEA Tandem Accelerator. The  $^{257}\text{No}$

**Fig.6-6  $\gamma$ -ray spectrum of  $^{257}\text{No}$**

Four  $\gamma$ -rays and characteristic X-rays associated with the  $\alpha$  decay of  $^{257}\text{No}$  were observed.

**Fig.6-7 Quantum states in  $^{257}\text{No}$  and  $^{253}\text{Fm}$**

Energies and spin-parities of excited states of  $^{253}\text{Fm}$  as well as the ground state of  $^{257}\text{No}$  were identified for the first time.

nucleus decays with an  $\alpha$ -particle emission with a half-life of 25 s, and its  $\alpha$ -particles and accompanying  $\gamma$ -rays were measured with high efficiency (Fig.6-5). In previous studies for superheavy nuclei, only a few or at most 100  $\alpha$ -particles could be detected. In this study, we have detected 5000  $\alpha$ -particles of  $^{257}\text{No}$  and observed 4  $\gamma$ -transitions in coincidence with these  $\alpha$ -particles (Fig.6-6). As a result, excited states of the daughter nucleus fermium-253 ( $^{253}\text{Fm}$ ) have been established as shown in Fig.6-7, and spin-parities of the ground state of  $^{257}\text{No}$  as well as the excited states of  $^{253}\text{Fm}$  have been identified for the first time.

This is the first successful  $\gamma$ -ray measurement and first spin-parity assignment for such heavy nuclei. The present result revealed that the spin-parity of the ground state of  $^{257}\text{No}$  is different from that expected. The experimental identification of quantum states in superheavy nuclei enables us to test the validity of various theoretical calculations. This is a great advance in elucidating the shell structure of superheavy nuclei.
